ABSTRACT

Termitecidal and fungicidal activities of wood vinegar from *Cinnamomum parthenoxylon* (CP) stem wood have been evaluated against *Coptotermes curvignathus* and wood rotting fungi (*Schizophyllum commune* and *Fomitopsis palustris*). The utilized CP wood vinegar was produced in the operating temperature range 250–300°C pyrolysis. A no-choice test was applied for evaluating termitecidal activity with 33 active termites and antifungal activity using the agar media assay. The result showed that an increase in the concentrations of CP wood vinegar significantly raised the mortality of termite. CP wood vinegar showed high termitecidal activity, organic acids (acetic acid 42.91%, 3-butenoic acid 6.89%, butanoic acid, 2-propenyl ester 2.26%), and ketones (1-hydroxy-2-propanone 5.14%, 3-methylcyclopentane-1,2-dione 2.34%) might be largely contributed to termitecidal activity in addition to other minor components. Furthermore, CP wood vinegar exhibited significant inhibition of fungal growth. These data showed that CP wood vinegar was more toxic to white-rot fungi (*S. commune*) than brown-rot (*F. palustris*). The results suggested that phenolic compounds from lignin degradation were responsible for good antifungal activity.

Keywords: wood vinegar, *Cinnamomum parthenoxylon*, termitecidal activity, GC-MS, fungicidal

1. INTRODUCTION

Some species of termites and rotting fungus are potential wood-destroying organisms thereby, leading to the economic loss of building materials. According to Kuswanto *et al.* (2015), subterranean termites are the most important wood pest in the world, with Formosan subterranean termite (*Coptotermes*) causing extensive damages in Asian countries. While, the white

and brown rotting fungus plays an important role in damaging all wood components such as lignin, cellulose, and hemicellulose (Blanchette, 1995; Yoon *et al.*, 2018).

Currently, a restriction has been placed on the application of insecticide and fungicide in preventing termitecidal and fungicidal activities on woods due to their adverse effect on human health and the surrounding environment. However, new safer treatment procedures have been investigated for practical use (Hadi *et al.*,

2018) with the development of pest control agents such as pyrethroids from *Chrysanthemum* genus and azadirachtin from *Azadirachta indica* with mild modes of action and are generally no persistent. Thus, plant-derived natural products are promising alternatives for pest control agents for now and near future (Casida *et al.*, 1983; Sidi *et al.*, 2012; Mun and Nicholas, 2017).

Wood vinegar, also called pyroligneous acid, liquid smoke, pyrolysis water, smoke water, lignocelluloses biomass bio-oil, wood distillate or mokusaku, is a product processed by high-temperature carbonization of wood/biomass with absent of oxygen and has been widely used as a wood preservative, fungicide, repellent, insecticide, and herbicide (Tiilikka *et al.*, 2010; Arsyad *et al.*, 2019).

Previously, we reported termiticidal activity of *Toona sinensis* wood vinegar against *Coptotermes curvignathus* and its chemical components. *T. sinensis* wood vinegar showed strong termiticidal activity (Adfa, 2017a). *T. sinensis* wood vinegar contains 40 constituents that were characteristic by GC-MS data. The organic compounds of *T. sinensis* wood vinegar were classified into carboxylic acids, phenols, ketones, amides, aldehydes, furans, esters, alcohols, a sugar derivative, and ether. The contents of organic fraction of *T. sinensis* wood vinegar which largely acetic acid (57.43%) might act for the termiticidal activity.

Wood vinegar was obtained by 475°C pyrolysis reactor of a mixture of pine, spruce and fir wood particles showed a strong inhibiting activity of *Trametes versicolor*, *Aspergillus niger* and *A. fumigatus*. The chemical components of the softwood mixture was found to have high concentrations of catechol and 4-methyl catechol (Suresh *et al.*, 2019). Coconut shells and coir are used as raw materials to produce wood vinegar in Thailand. The wood vinegars were obtained from the carbonization process with temperatures ranging between 300-400°C. Wood vinegar from coconut shells and the mixture of coconut shells and

coir exhibited high termiticidal activity against workers termite of *Odontotermes* sp. at a dilution of 1:50. Acetic acid, formaldehyde, and phenols content of wood vinegars assume are the major cause of mortality of pest (Wititsiri, 2011).

Cinnamomum parthenoxylon belong to the Lauraceae family, and its crude methanol extract of leaves showed good termiticidal and antifeedant activity against *Coptotermes curvignathus* (Adfa *et al.*, 2017b). Coumarin, flavonoids, benzenoids compounds which have been identified and isolated from the crude methanol extract might be responsible for its activity (Pardede *et al.*, 2017; Wei *et al.*, 2017). In continuing our research on potential *C. parthenoxylon* as a biopesticide, we would like to investigate the essential oil, extract, fractions, isolated compounds, and wood vinegar of *C. parthenoxylon* against termite and wood decay fungus.

To the best of our knowledge, until now no reported the anti-termite and anti-wood decay fungi activities of wood vinegar produced from stem wood of *Cinnamomum parthenoxylon*. In this study therefore, we evaluated the termiticidal activity of *C. parthenoxylon* wood vinegar against *C. curvignathus* as well as its antifungal activity against wood-rotting fungi *Schizophyllum commune* and *Fomitopsis palustris*.

2. MATERIALS and METHODS

2.1. Materials

Stem wood of *Cinnamomum parthenoxylon* (CP) was collected around the main Campus University of Bengkulu. Sample was cut into chip and then air-dried in the Organic Chemistry Laboratory, Department of Chemistry, University of Bengkulu. The material comprising of NaOH, Oxalic acid anhydrous, Phenolphthalein, and Whatman No. 3 filter paper were purchased from Sigma-Aldrich, while Methanol and Potato Dextrose Agar (PDA) were purchased from Merck.

2.2. Pyrolysis and chemical components analysis of *Cinnamomum parthenoxylon* stem wood

Wood vinegar was produced from burning air dried stem wood of *Cinnamomum parthenoxylon* (300 g) in a pyrolysis reactor at 250-300°C temperatures. This process was repeated three times with the collected wood vinegar stored at room temperature for two months to separate tar (Zhai *et al.*, 2015), and the wood vinegar was weighed to calculate the yield.

The analysis of chemical components of *C. parthenoxylon* (CP) wood vinegar was carried out using GC-MS (Agilent Technologies 7890A GC with 5975C MS). MS run with hydrogen as carrier gas. A column HP-5MS (Agilent 19091S-436) with 30 m length, id 0.25 mm and 0.25 µm film thickness was used as column and the maximum column temperature is 450°C. Front inlet mode: splitless with initial temperature 250°C, pressure 7.1282 psi, split flow 50 mL/min, and total flow 54 mL/min. The mass spectrometer was operated in electron-ionization (EI) mode and the mass spectra were obtained by Acquisition mode scan of the mass range from 40 to 450.

The wood vinegar chemical components were identified based on their retention time (RT), with the mass spectra compared to Wiley and NIST library data of the GC-MS system. The percentage of components was calculated by the GC peak area, refers to Adfa *et al.* (2017a).

2.3. Physicochemical properties

Organic acid contents of CP wood vinegar was determined by the acid-base titration with 0.001 N NaOH and expressed as acetic acid (%). The pH value of CP wood vinegar was measured by using a pH meter (HANNA HI-98107), while the density was measured by the pycnometer, odor and color were observed as well (Adfa *et al.*, 2017a).

2.4. Termiticidal activity

Workers and soldiers of *Coptotermes curvignathus* Holmgren were collected from trees were attacked by termites around University of Bengkulu, and the termite was identified at School of biological sciences and technology, Institute Technology Bandung, Indonesia. The colony was maintained at 28°C ± 2 and 80% ± 5 RH in a container, and they fed wet filter paper until used for the test. A no-choice test was employed for evaluating termiticidal activity of CP wood vinegar according to the previous method. The concentrations of CP wood vinegar were prepared to 0% (solvent only, control), 2%, 4%, 6% and 8% (sample mass (mg)/filter paper mass (mg)) × 100%). The samples were dissolved in 500 µL ethanol and then the resulting solution was applied to filter papers (Whatman No. 3, diameter 90 mm), and the papers were dried overnight at room temperature, continued two hours in a vacuum desiccator. The four replications were performed for each concentration. Subsequently, each dried filter paper was put in Petri dishes (90 mm in dia × 20 mm height), then thirty workers and three soldiers termites from the adult of active *Coptotermes curvignathus* were added. The Petri dishes were then placed on a wet cloth in a plastic tray and kept in a dark room at room temperature (28°C ± 2) and 80% ± 5 RH for 8 days. The number of termites dead was counted daily, with the termiticidal activity was evaluated from their average mortality rate (%). For statistical analysis, Duncan's multiple comparison test were used to evaluate differences in percent mortality of termites. The results with $P < 0.05$ were considered significant, with the calculations performed using statistical software SPSS 16.0 (Adfa *et al.*, 2012; Adfa *et al.*, 2013, 2017c).

2.5. Antifungal activity

The antifungal assay was conducted according to Kartal *et al.* (2004) and Oramahi *et al.* (2018) with

modification. Cultures of a brown-rot fungi *Fomitopsis palustris* and a white-rot fungi *Schizophyllum commune* 7 days old grown on potato dextrose agar (PDA) plates at 25°C were used as inoculating. CP wood vinegar 0, 0.2, 0.5, 0.7, 0.9, and 1% v/v in PDA media sterile was poured 15 mL into Petri dishes (90 mm dia. × 20 mm high) and left to cool in room temperature, while the PDA only (0% wood vinegar) was used as control. The Petri dishes were then centrally inoculated with a single plug of each fungus after cutting with a cork-borer at 5 mm diameter. Three replicates were conducted for each condition. The treated and control dishes were incubated in a dark incubator at 25°C until the growth of fungi in controls reached the edge of the dishes and the diameter of the mycelium growth was measured. The percentage of mycelium inhibition rate was calculated by following equation:

$$I = [(C-T)/C] \times 100\% \quad (1)$$

Where I =inhibition percentage; C =diameter of mycelium growth in control Petri dishes (mm); and T =diameter of mycelium growth in treated Petri dishes that containing the wood vinegar (mm).

3. RESULTS and DISCUSSION

3.1. Wood vinegar of *Cinnamomum parthenoxylon* and its properties

The characteristics and properties of wood vinegar are primarily influenced by the type of carbonaceous feedstocks as well as pyrolysis time and temperature pyrolysis (Mathew and Zakaria, 2015; Fengel and Wegener, 2011). The wood vinegar of *Cinnamomum parthenoxylon* (CP) stem wood was yellowish-brown in color, smoky in odor and transparent with yield 24.88%. The total organic acids contained were 9.59%, with density of 1.042 g cm⁻³, and pH value of 3.57.

Wada (1997) reported the criteria for good quality of the wood vinegar is using pH around 3, specific gravity of 1.010–1.050 g·mL⁻¹, with color visually pale yellow, bright brown or reddish-brown, smoky odor, transparent visually with no suspended matter, and the dissolved tar content not more than 3%. According to Wada (1997), CP wood vinegar appeared to be of good quality in terms of odor, color, gravity, and transparency, except for pH value 3.5 that meet the Japanese standards.

The components of the CP wood vinegar were identified by GC/MS. The GC chromatogram of CP wood vinegar showed 42 chemical components (Fig. 1), and 30 components belonging to the seven groups were identified base on Mass Spectra data (Table 1). It also indicated that CP wood vinegar consist of carboxylic acids (53.76%, 9 components), phenols (11.62%, 6 components), ketones (9.19%, 5 components), furans derivatives (6.41%, 4 components), amines (3.4%, 2 components), a few hydrocarbon aromatics (1.39%, 2 components), and alcohols (0.90%, 1 component). The result showed that organic acids were the primary components of CP wood vinegar, while acetic acid was the largest

13.575	3,5-Dimethoxy-4-hydroxyphenylacetic acid	0.34

component (42.91%) among 9 kinds of organic acids. Following organic acid phenols were the secondary compounds in CP wood vinegar, among them 2,6-dimethoxyphenol (5.51%) was identified as the major phenol compound.

The chemical profiles of CP wood vinegar were an

agreement with Zhai *et al.* (2015) that organic acids, phenolic compounds, ketones, aldehydes, benzene and its derivatives were the major components obtained at the temperature ranging 90–290°C pyrolysis range. Many studies have been conducted on the characterization of wood vinegar obtained from both slow and fast pyrolysis with the results dependent on the wood species and pyrolysis temperatures (Guillén, and Manzanos, 2005; Mun *et al.*, 2007; Mohan *et al.*, 2006, Adfa *et al.*, 2017a). In addition, previous study was conducted on wood vinegar from *Toona sinensis* (TS) sawdust and produced in the pyrolysis reactor under conditions similar to this study. The results showed differences in physicochemical properties, with lower carboxylic acid and higher phenol components compared to TS wood vinegar. Lignocellulose materials such as wood are mainly composed of cellulose, hemicellulose, and lignin. The acetic acid to have originated from the acetyl groups in the hemicellulose (Kartal *et al.*, 2004) and was the largest content of the wood vinegar obtained in the current study, whereas phenolic basically results from the thermal degradation of lignin (Mohan *et al.*, 2008).

3.2. Antitermite and antifungal activities of *Cinnamomum parthenoxylon* wood vinegar

In this study, the daily termite mortality of *C. curvignathus* with CP wood vinegar was determined for 8 days by using the no-choice feeding test, with the results presented in Fig. 2 and their statistical analysis shown in Table 2. The mortalities were significantly increased with concentrations CP wood vinegar increased. At a concentration of 2%, all termites were dead after 8 days, while at 4%, and 6% the number of days reduced to 7. The filter paper treated with 8% wood vinegar showed the fastest termite mortality among all concentrations and control, 100% termite died on average after 6 days, and the significant difference at $P<0.05$

Table 2. Statistical analysis of termiticidal activity of *Cinnamomum parthenoxylon* wood vinegar

Sample	Mortality of termite (%) ^a over 1-8 days							
	1	2	3	4	5	6	7	8
Control	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00

Wood vinegar [6%]	5.30	12.12	27.27	54.55	77.27	93.94	100	100
Wood vinegar [8%]	9.09	16.67	47.73	69.70	87.88	100	100	100
	AB	AB	CD	EF	HI	KL	M	M

^a Numbers followed by different letters (A–M) on mortality (%) are significantly different at the level of $P<0.05$ according to Duncan multiple comparison test, n=5 using 33 termites per replicate.

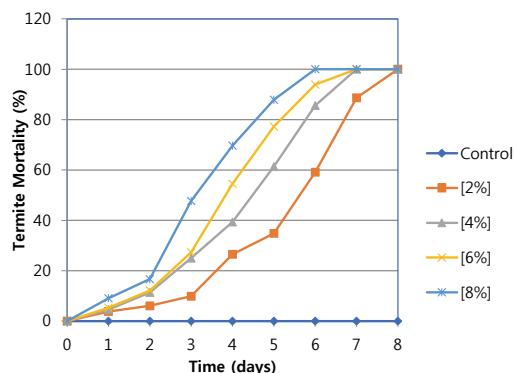

Fig. 2. Termiticidal activity of *Cinnamomum parthenoxylon* wood vinegar.

with Duncan's multiple comparison test to control and concentrations of 2 and 4% at 6 days. However, no significant difference with a concentration of 6% was observed on the 6 days. Organic acids (acetic acid 42.91%, 3-butenoic acid 6.89%, butanoic acid, 2-propenyl ester 2.26%), and ketones (1-hydroxy-2-propanone 5.14%, 3-methylcyclopentane-1,2-dione 2.34%) might be largely contributed to termiticidal activity in addition to other minor components.

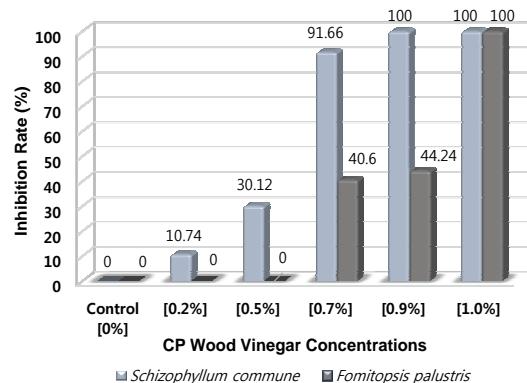

The termiticidal activity was performance consistent with the concentration of total acid in the wood vinegar, in good agreement with the previous report which used

the wood vinegar made from *Toona sinensis* (TS) sawdust. TS wood vinegar showed strong termiticidal activity against *Coptotermes curvignathus*, evidenced at a concentration of 8% all termites dead after 3 days tested. It also contained 57.43% acetic acid which is responsible for the termiticide activity (Adfa *et al.*, 2017a). According to Oramahi and Yoshimura (2013), the wood vinegar obtained from *Vitex pubescens* wood exhibited termiticidal activities against *Reticulitermes speratus* and *Coptotermes formosanus*, and its total acid concentration influenced anti termite activity. Yatagai *et al.* (2002) reported that acetic acid is the largest content of wood vinegar made from mixed chips of *Cryptomeria japonica* and *Pseudotsuga menziesii*; *Quercus serrata* and *Pinus densiflora* exhibited high termiticidal activity against *R. speratus*.

CP wood vinegar exhibited significant inhibition of the fungal growth. The mycelium growth of *Schizophyllum commune* and *Fomitopsis palustris* on the test medium and control is shown in Table 3, while the antifungal activity is summarized in Fig. 3. In addition, its inhibition growth against white-rot fungi (*S. commune*) at the various concentrations of 0, 0.2, 0.5, 0.7, 0.9, and 1% v/v were 0, 10.74, 30.12, 91.66, 100, and 100%, respectively. While, the inhibition growth

Table 3. The mycelium growth of *Schizophyllum commune* and *Fomitopsis palustris* on the test medium and control

Wood rotting fungi	Control [0%]	Wood vinegar [0.2%]	Wood vinegar [0.5%]	Wood vinegar [0.7%]	Wood vinegar [0.9%]	Wood vinegar [1.0%]
<i>Schizophyllum commune</i>						
<i>Fomitopsis palustris</i>						

**Fig. 3.** Antifungal activity of *Cinnamomum parthenoxylon* wood vinegar against wood rotting fungi (*Schizophyllum commune* and *Fomitopsis palustris*).

against brown-rot fungi (*F. palustris*) at the same concentrations tested were 0, 0, 0, 40.6, 44.24, and 100% respectively.

The inhibition growth of CP wood vinegar against *S. commune* at low concentrations of 0% until 0.5% v/v showed a steady increased from 0% to 30.12%. The growth further increased sharply after the concentration changed to 0.7%, three-fold gain compared with 0.5%. Interestingly, there was 100% inhibition growth when the CP wood vinegar concentration changed to 0.9 and 1%. In contrast, at a low concentration test

from 0 to 0.5% v/v, the CP wood vinegar failed to inhibit the mycelium growth of *F. palustris*, whereas moderate growth of 40.6% and 44.24% when the concentration changed to 0.7 and 0.9% v/v. Interestingly, the inhibition growth of *F. palustris* increased sharply to 100% at a 1% concentration. These data showed that CP wood vinegar was more toxic to white-rot fungi than brown-rot fungi using the agar media assay.

Celimene *et al.* (1999) stated that stilbenes (pinosylvin, pinosylvin monomethyl ether, and pinosylvin dimethyl ether) were more toxic to white-rot fungi than brown-rot fungi using the agar media assay. According to Oramahi *et al.* (2018), the wood vinegar produced from the oil palm trunk at pyrolysis temperature 350°C greatly inhibited white-rot fungi growth (*T. versicolor*) at concentrations of 1.0 and 1.5%. However, higher concentrations were required to inhibit *F. palustris* growth (brown rot fungi).

Another report by Theapparat *et al.* (2014) that antifungal activity of wood vinegar from *Eucalyptus camaldulensis*, *Leucaena leucocephala*, *Azadirachta indica*, *Hevea brasiliensis* (rubberwood) and *Dendrocalamus asper* (bamboo) against two white rot fungi (*Trametes versicolor* and *Rigidoporus amylospora*), a brown rot fungus (*Gloeophyllum trabeum*) and a sapstain fungus (*Botryodiplodia theobromae*) was investigated.

All wood vinegar exhibited antifungal activities, among them wood vinegar made from bamboo and rubberwood showed greater activity which had higher total phenolic concentrations.

Many studies have also suggested that phenolic compound from lignin degradation were responsible for good antifungal activity (Kartal *et al.*, 2004; Nakai *et al.*, 2007; Mohan *et al.*, 2008). There is ongoing research to investigate the efficacy of CP wood vinegar as a repellent agent against *C. curvignathus* and inhibiting of *T. versicolor* and *Rhizopus oryzae* growth.

4. CONCLUSION

In conclusion, the production of wood vinegar from *C. parthenoxylon* stem wood using a pyrolysis reactor at 250-300°C temperatures exhibited promising antitermite and anti-wood decay fungi activities. The growth of *S. commune* and *F. palustris* at 0.9 and 1% concentrations, were successively inhibited 100% by CP wood vinegar. At the lowest concentration tested (2%) 100% termite dead after 8 days tested, when the concentration raised to 8% all termite dead on average after 6 days. The organic acid and phenols might be responsible for both activities. CP wood vinegar has the potential to prevent attacks by *C. curvignathus*, *S. commune* and *F. palustris*. The next study need to further investigate which components of wood vinegar are responsible for antitermite and anti-wood decay fungi activity singly.

ACKNOWLEDGMENT
